

Representation of Trust Opinions in Messages and TAF

Artur Hermann, Dennis Eisermann, Nataša Trkulja, Frank Kargl
Institute of Distributed Systems, Ulm University

Representation of Subjective Logic Opinions in the TAF

- Subjective Logic (SL) Opinions form the basic unit of trust representation in Subjective Logic and the TAF
- They express the opinion of an opinion holder on a proposition; which in the TAF represents the trustworthiness of data or an entity
- Therefore ω_X^S represents the opinion of subject S on statement X
- Example: ω_C^{V1} represents the opinion of vehicle V1 that a received CAM message C contains trustworthy information
- A Subjective Logic Trust Network allows to reason over complex and transitive trust relationships using fusion and trust discounting operators

SL Trust Network Example

- For binomial propositions with $\omega_X^S | X = \{x, \bar{x}\}$ the opinion is represented by the tuple $\omega_X^S = (b, d, u, a)$ where $0 \leq (b, d, u, a) \leq 1$ and $b + d + u + a = 1$
- b represents the belief of X to be true ($X = x$)
- d represents the disbelief of X to be false ($X = \bar{x}$)
- u represents the uncertainty in the assessment of X due to lack of conclusive evidence
- a represents the prior probability of X to be true in the total absence of evidence to assess

Challenge 1: Including SL opinions in V2X messages increases channel load and can lead to packet loss

- Exchange of opinions is required for federated trust assessment in CCAM systems
- These should be included in and sent together with standard messages like CAMs, DENMs, or CPMs

Challenge 2: Limited accuracy of opinion representation introduces errors in trust assessment and reason

- In CPUs, (b, d, u, a) are typically represented as IEEE 754 Binary64
- When communicating opinions between nodes, we typically need to limit representation even further, using for example only 8, 16, or 32 bit per value
- Subjective logic operations inevitably introduce errors that can accumulate as the trust network grows in depth
- We conducted extensive analytical and simulation-based analyses to understand the nature and extent of these errors
 - For this purpose, we used interval arithmetic and simulations implemented in Haskell
 - We also considered even more restricted transfer encodings in messages
- Based on these insights, we propose guidelines for SL trust networks and implementation of SL operators
- We also propose integration and representations of SL opinions in standard messages

Problem analysis

- Where to add SL opinions in CAMs?

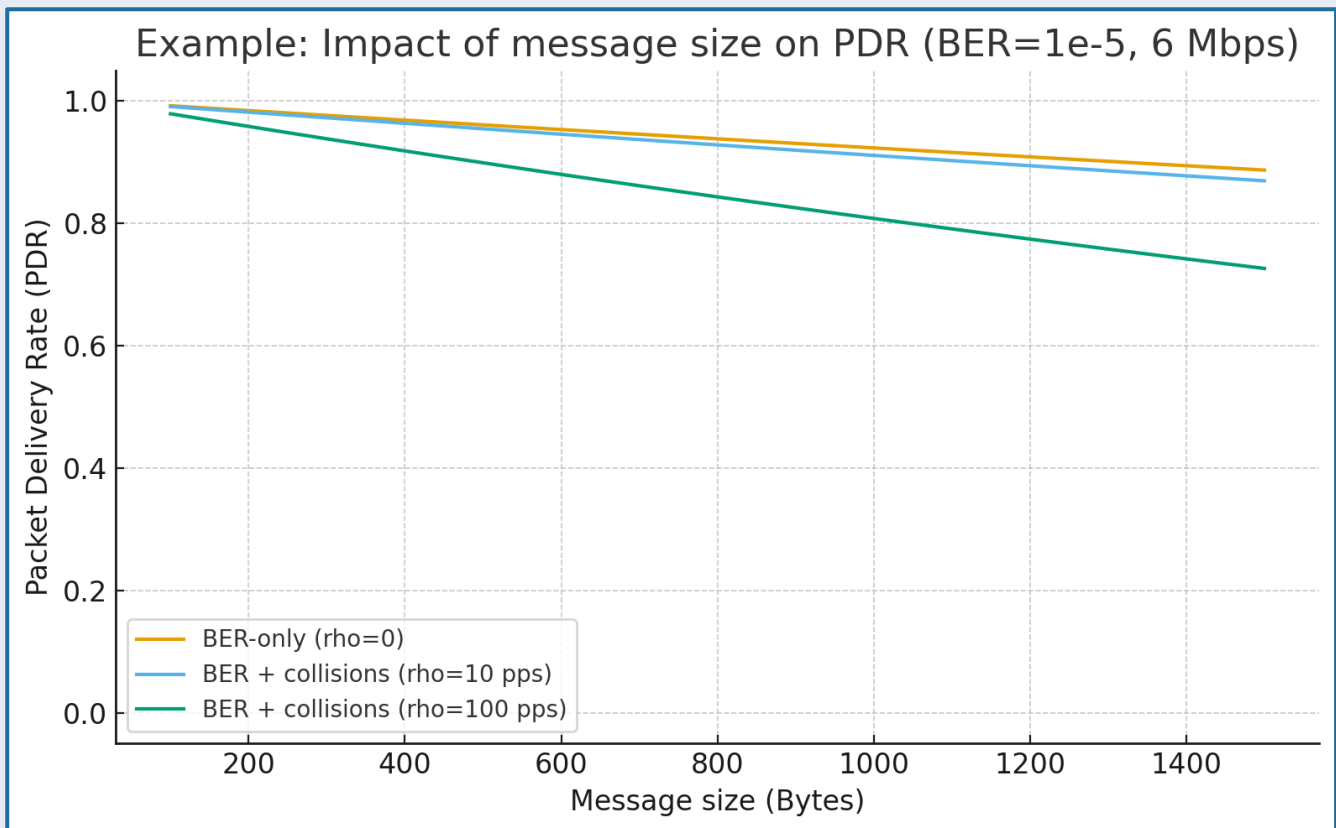

CAM DoubleWord				
Comment CAM basic container mandatory	Byte 0	Byte 1	Byte 2	Byte 3
Start of Message min 4 Hz, max 10 Hz	8ProtocolVersion	8MessageID	48GenTimeLo	48GenTimeHi
opinion per data item(s)	32PositionID			
	32Longitude in microdegrees			
	32Latitude in microdegrees			
	24Elevation			
256StreetName deleted CR-803	16Heading	16VehicleSpeed		45Ch4HdConf
VireLaneAttributes up to 256 Bit ??	8VireLaneCount	8VireLaneWidth	16PosConf4MinConf	4PosConf4ElevConf
32RoadSegmentID deleted CR 8-03	16PosConf4DirConf	4MayConf4MinConf	4PosConf4ElevConf	4PosConf4ElevConf
End of CAM basic container mandatory, length ca. 47 Bytes	16YawRate	11CurvatureChange, 4CurConf	8CauseCode	
	16Curvature	11CurvatureChange, 4CurConf	8CauseCode	
	12LongAcceleration, 4LAConf	8CauseCode	6AccelerationContr	
	12LongAcceleration, 4LAConf	8CauseCode	6AccelerationContr	

CAM DoubleWord						
Comment CAM static container optional	Byte 0	Byte 1	Byte 2	Byte 3

CR CD-26 Remove DistanceToStopLine, CR CD-30 Rem Prio	8TurnAdviceDir	16TurnAdviceDistance	16TurnAdviceDistance			
CR CD-36 Remove WipeSignalFront						
End of CAM static container optional, length ca. 37 Bytes						

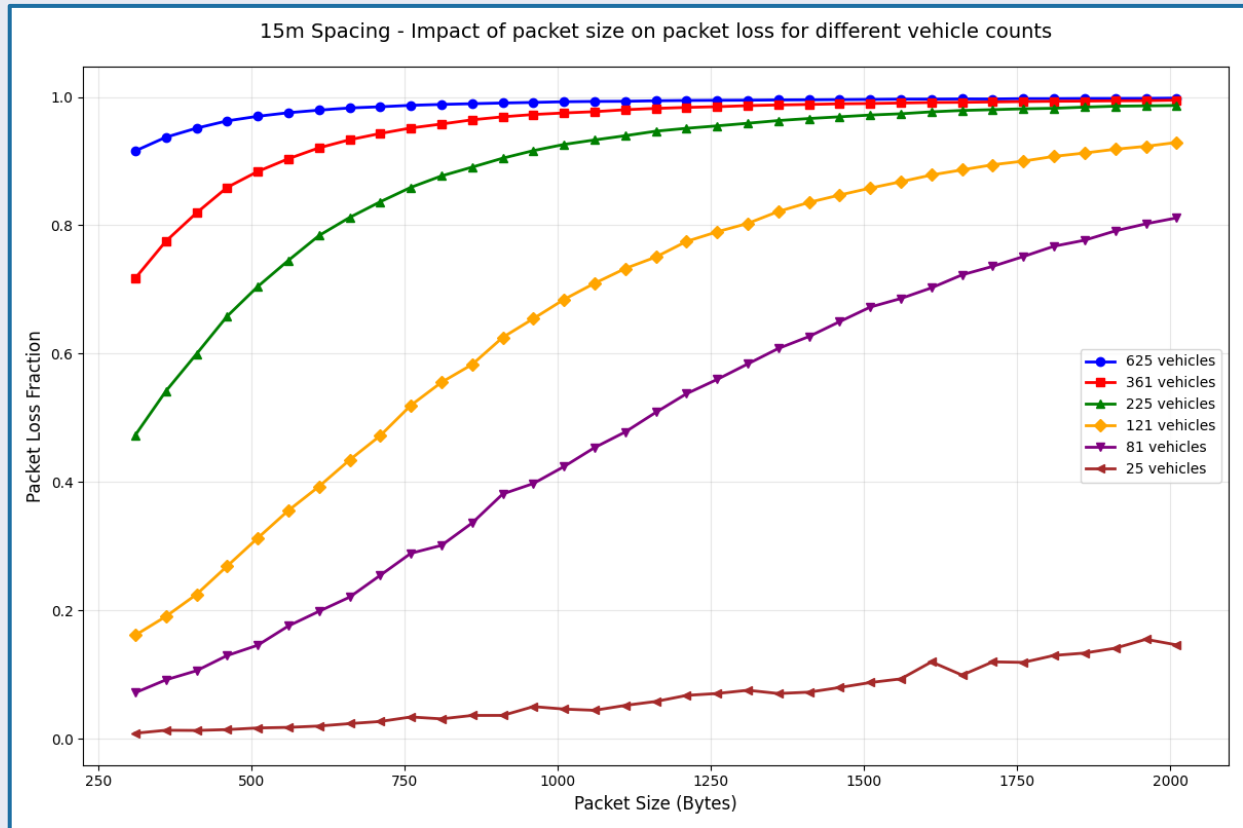

opinion per container

opinion per CAM

- Exchange of opinions is required for federated trust assessment in CCAM systems
 - should be included in and sent together with standard messages like CAMs, DENMs, or CPMs
 - expressiveness increases the more fine-granular opinions you include
 - also makes the message size grow proportionally
- Larger messages affect message delivery success, due to:
 - Larger channel occupation and larger channel access latency
 - Increased risk of bit errors during transmission
 - Increased risk of collisions due to CMA/CA random access with fixed backoff window
 - Increased risk of collisions due to hidden terminal constellations

Analysis based on analytical model of IEEE 802.11p: effects of BER and collisions on PDR

Simulations based on OMNET++ / VEINS / SUMO document effect of message size on PDR

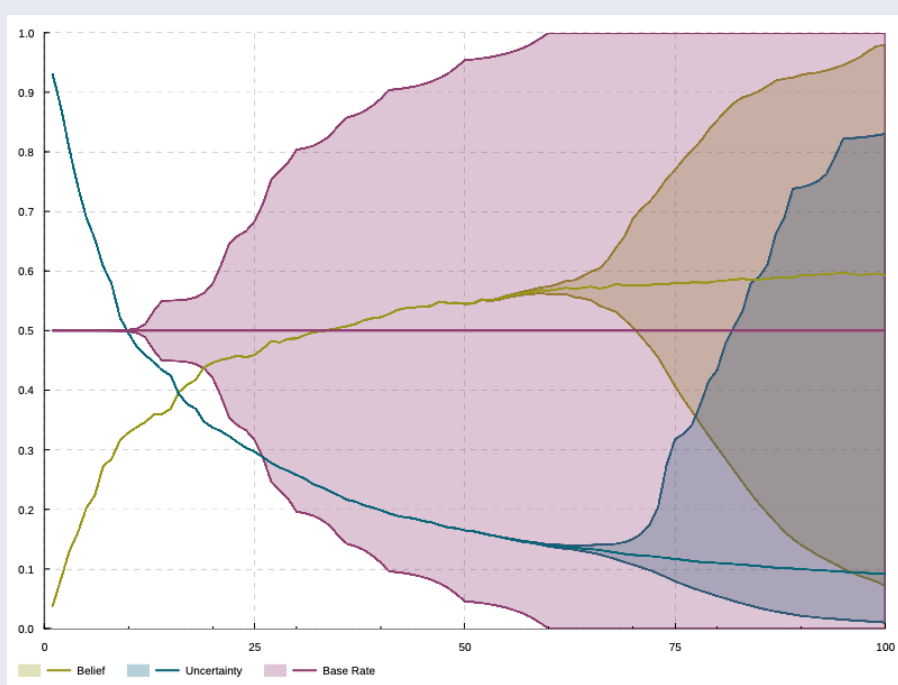

Simulation results

- Approach: repeated application of SL operation (different fusion operators & trust discounting) to identify when calculations become unstable
- Experiment 1: (Averaging) Fusion of opinions with binary32 representation show sudden shift from one extreme to the other

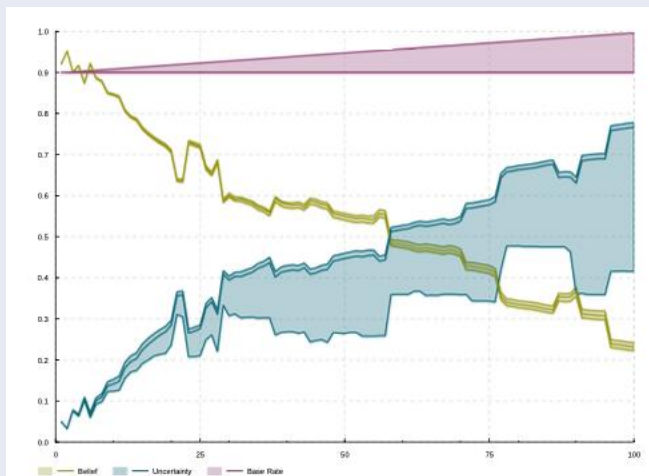

- Scenario: Jury-MostlyYes-Binary32-100
- Not observed with binary64

- Experiment 2: Repeated cumulative fusion of opinions with high uncertainty leads to substantial growth of confidence intervals
- Scenario: Reputation-MostlyUnknown-Binary64-100

- Experiment 3: Transmission as tuple (b, u, a), as fixed-point numbers of type UQ0.16 proofs stable in realistic scenarios (here: platooning)
- Scenario: PlatoonUQ0_16-SpanishInquisition-Binary64-100
- For smaller networks, the packed representation $\sim (b: UQ0.11, u: UQ0.11, a: UQ0.10)$ (32 bits total) might be sufficient

Conclusion 1

- Size of messages should be kept below 400 bytes in high-load scenarios
- Opinions per data field are not practical (considering current message sizes w/o opinions including already message payloads, headers, and security)
- More evaluations are required that investigate efficient encodings of opinions and also the accuracy of trust assessment that is achievable when having opinions per container or per message

Conclusion 2

- Normalize results and intermediate values (recalculation of disbelief as $d = 1 - b - u$)
- binary64 for internal representation and UQ0.16 for transfer encoding recommended
- Many learnings for structure of trust networks
 - Avoid cumulative fusion of opinions with high uncertainty
 - Keep diameter of trust graphs < 20 (common in practice)
- Novel results and insights on SL; publication pending
